Principles of Database Systems (CS307)

Lecture 5: More on Join; Set Operators; Subqueries

Ran Cheng

Department of Computer Science and Engineering Southern University of Science and Technology

- Most contents are from slides made by Stéphane Faroult and the authors of Database System Concepts (7th Edition).
- Their original slides have been modified to adapt to the schedule of CS307 at SUSTech.

More on Join

The Old Way of Writing Joins

- Use commas to separate the tables
 - Example: The solution for the same question in the previous slide
- A little bit history:
 - join was introduced in SQL-1999 (later than this original way)
- Relationship to the relational algebra
 - Filtering based on the Cartesian product
 - movies × credits × people

The Old Way of Writing Joins

- Problems in the old way:
 - If you forget a comma, it will still work sometimes (interpreted as "renaming")
 - The semantic meaning of the where clause here is a little bit different from the where we introduced before
 - (join key vs. filtering condition)
 - If you forget where, the query will not return an error but to end up with HUGE amount of rows
 - #movies * #credits * #people

More about Join

Recall: how we used Join last week?

Show names of actors and directors for Chinese movies

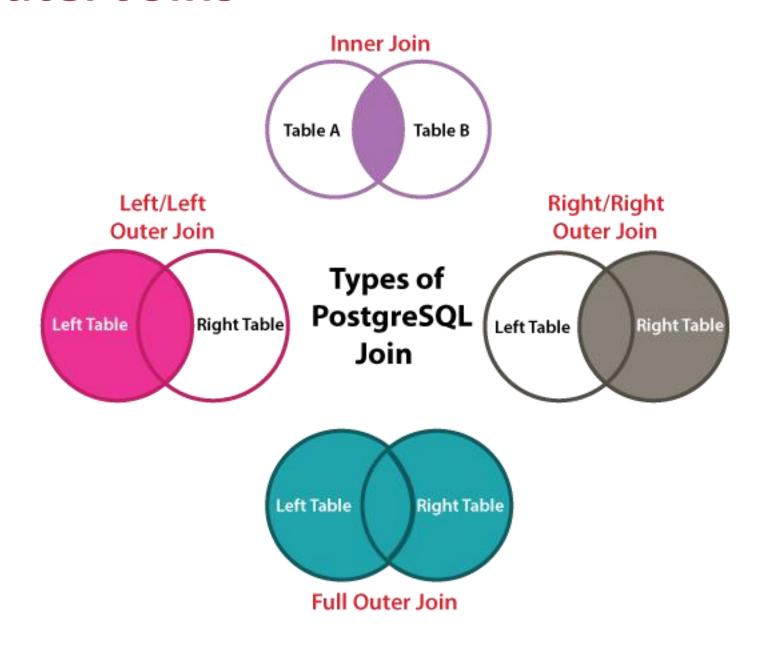

```
    people

                                movies
                          Novieid
P peopleid
first_name varchar(30)
                          ■ title
surname varchar(30)
                          ■ country
                          year_released integer
■ born
II died
                          II runtime
■ gender
    peopleid
                             movieid
                   m credits
                movieid integer
                peopleid integer
                ■ credited_as char
```

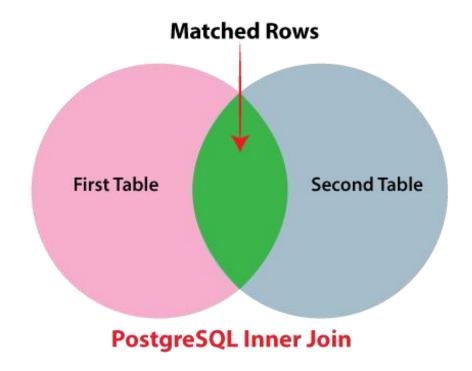

```
select m.title, c.credited_as, p.first_name, p.surname
from
    movies m join credits c on m.movieid = c.movieid join people p on c.peopleid = p.peopleid
where m.country = 'cn';
```

More about Join: Inner and Outer Joins

- So far, we only consider the rows with matching values on the corresponding columns
 - However, there are more things you can do with join

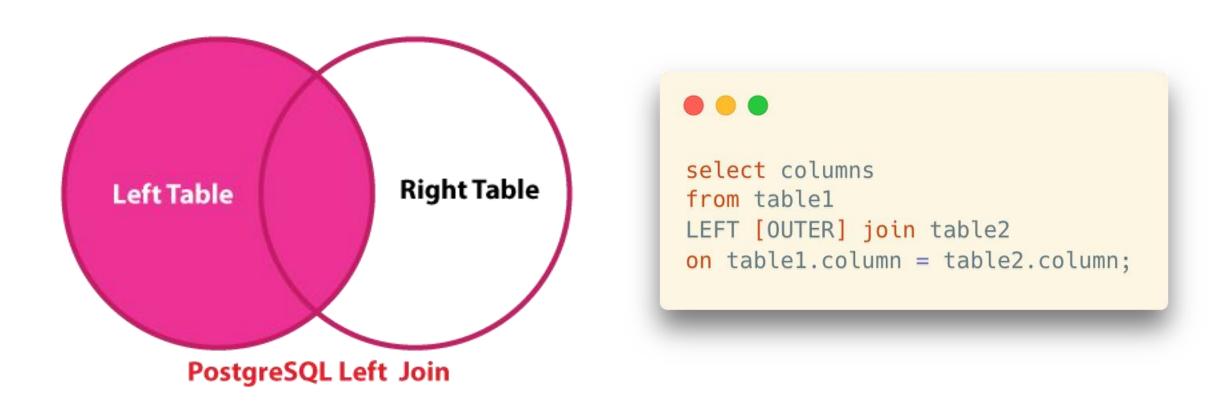

- Inner join
 - The default join type
 - Acturally, all examples before are considered inner joins
 - Only joined rows with matching values are selected

```
select title,
   country_name,
   year_released
   from movies
   join countries
   on country_code = country;
```

- Left outer join
 - All the matching rows will be selected
 - ... and the rows in the **left table** with **no matches** will be **selected** as well

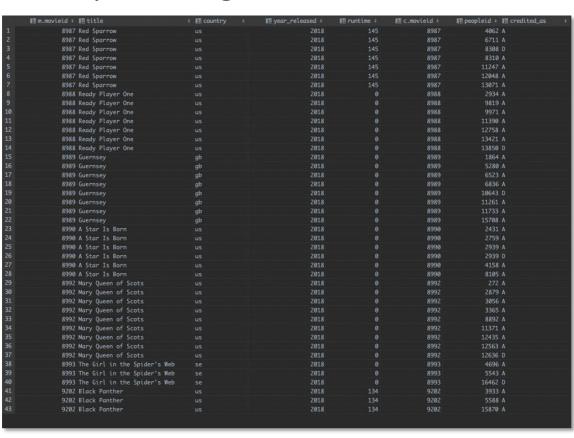

- Left outer join
 - Why? Why should we show the records in the left table with no matches?
 - Scenario: Movie Website (Douban, for example)
 - We cannot just ignore the movies with no credit information
 - Instead, we should list them and also show that credit information is missing
 - Any other example?

- Left outer join
 - Example: there is a movie in 2018 where there is no credit information
 - #9203 (A Wrinkle in Time)

```
✓ select * from movies where movieid = 9203;
```

- Left outer join
 - Example: there is a movie in 2018 where there is no credit information
 - #9203 (A Wrinkle in Time)
 - Inner join of all 2018 movies will not show any matching results for that movie

```
select *
from movies m join credits c
on m.movieid = c.movieid
where m.year_released = 2018;
```

- Left outer join
 - Example: there is a movie in 2018 where there is no credit information
 - #9203 (A Wrinkle in Time)
 - Inner join of all 2018 movies will not show any matching results for that movie
 - But, left (outer) join can give you a record for the movie (in the left table) where all righttable columns are null

Pay attention to the syntax:

- left join or left outer join
- But some databases recognize the outer keyword, some do not. Refer to the database manual if you meet any error.

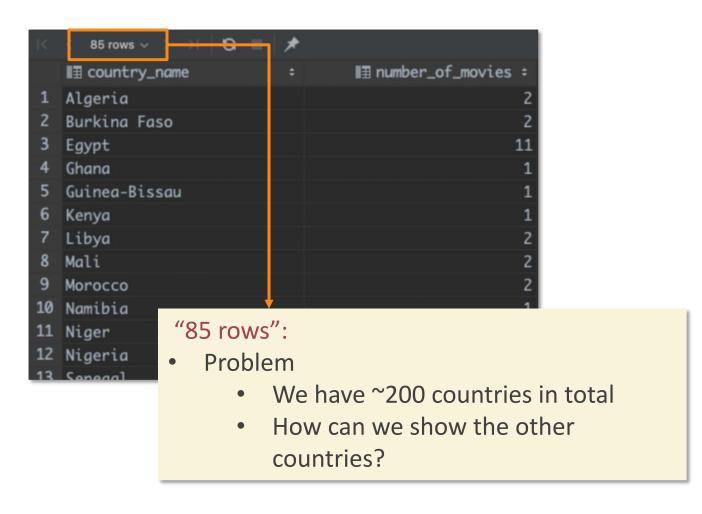

```
select * from movies m left join credits c on m.movieid = c.movieid
where m.year_released = 2018;
```

	III m.movieid ÷ III title	÷ III country	÷	■ year_released :	III runtime ÷	III c.movieid ÷	■ peopleid ÷ ■ credited_as	÷
41	9202 Black Panther	us		2018	134	9202	3933 A	
42	9202 Black Panther	us		2018	134	9202	5588 A	
43	9202 Black Panther	us		2018	134	9202	15870 A	
44	9203 A Wrinkle in Time	us		2018	109	<null></null>	<null> <null></null></null>	

- Left outer join
 - Another example: let's count how many movies we have per country (again)

- Left outer join
 - Another example: let's count how many movies we have per country (again)

```
select c.country_name, number_of_movies
from countries c join (
    select country as stat_country_code,
        count(*) as number_of_movies
    from movies
    group by country
) stat
on c.country_code = stat_country_code;
```

- Left outer join
 - All countries are here now
 - In addition, how can we replace nulls?

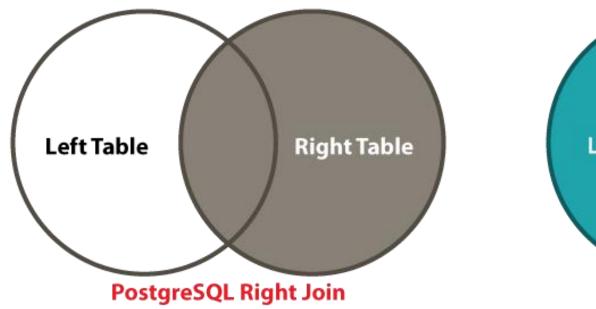

```
select c.country_name, number_of_movies
from countries c left join (
    select country as stat_country_code,
        count(*) as number_of_movies
    from movies
    group by country
) stat
on c.country_code = stat_country_code;
```

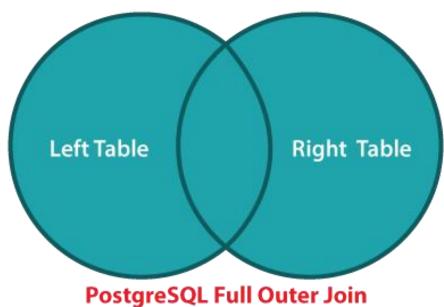

```

                                                     <null>
Eritrea
                                                     <null>
```

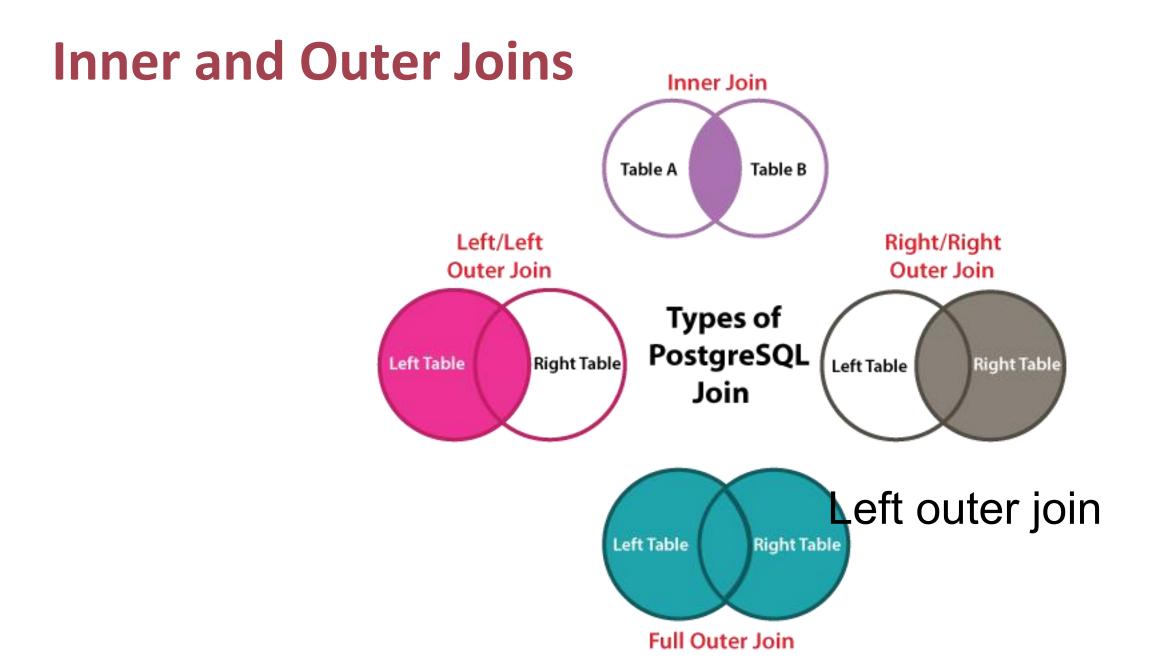

- Left outer join
 - All countries are here now
 - In addition, how can we replace nulls?
 - Add another CASE condition

	■ country_name ÷ ■ number_of_movies	‡
1	Algeria	2
2	Angola	0
3	Benin	0
4	Botswana	0
5	Burkina Faso	2
6	Burundi	0
7	Cameroon	0
8	Central African Republic	0
9	Chad	0
10	Comoros	0
11	Congo Brazzaville	0
12	Congo Kinshasa	0
13	Cote d'Ivoire	0
14	Djibouti	0
15	Egypt	11
16	Equatorial Guinea	0
17	Eritrea	0
18	Ethiopia	a

- Right outer join, full outer join
 - Books always refer to three kinds of outer joins. Only one is useful and we can forget about anything but the LEFT OUTER JOIN
 - A right outer join can ALWAYS be rewritten as a left outer join (by swapping the order of tables in the join list)
 - A full outer join is seldom used

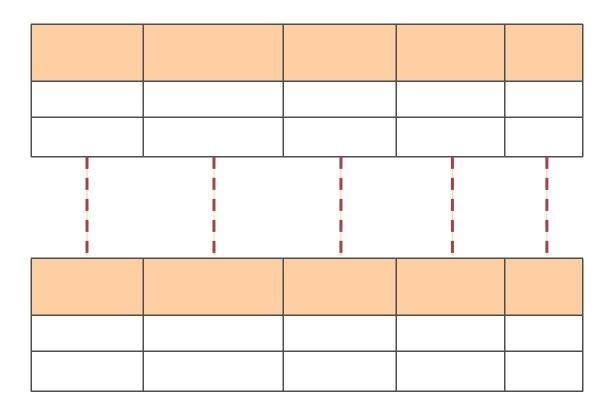

Can you describe different JOINs as in BRIEF lanugage as possible?

- Union
 - Takes two result sets and combines them into a single result set
- Union requires two (commonsensical) conditions:
 - They must return the same number of columns
 - The data types of corresponding columns must match.

- Union
 - Example: Stack US and GB movies together

```
select movieid, title, year_released, country
from movies
where country = 'us'
  and year_released between 1940 and 1949
union
select movieid, title, year_released, country
from movies
where country = 'gb'
  and year_released between 1940 and 1949;
```

	.∰ movieid ÷ .⊞ title	‡	.⊞ year_released ÷	📭 country 🗧
1	3840 The Secret Life of Walter Mitty		1947	us
2	678 The Ox-Bow Incident		1943	us
3	3174 The Red House		1947	us
4	5152 Minesweeper		1943	us
5	1487 Kiss of Death		1947	us
6	3408 Ministry of Fear		1944	us
7	2543 The Way to the Stars		1945	gb
8	5341 All Through the Night		1942	us
9	1435 They Live by Night		1948	us
10	2644 Criminal Court		1946	us
11	7250 The Seventh Veil		1945	gb
12	7341 Mr. Lucky		1943	us

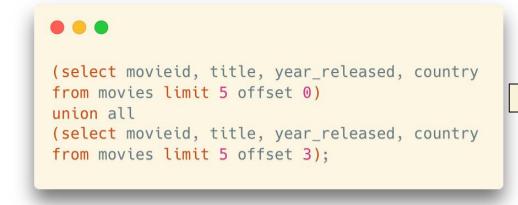

- Union
 - Usage scenario: combine movies from two tables, one for standard accounts and one for VIP accounts
 - We don't want to miss the "standard movies" for the VIP accounts

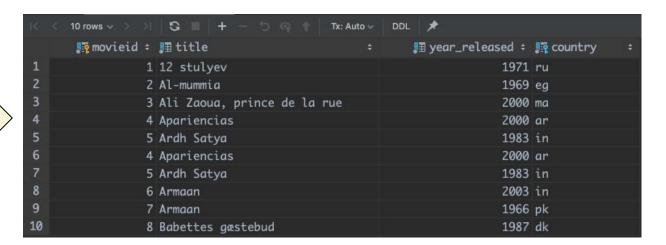

- Union
 - Warning: union will remove duplicated rows
 - Instead, you can use union all

- The LIMIT clause restricts the number of rows returned by a query.
- The OFFSET clause is used to skip a specified number of rows before starting to return rows from the query.

Why we need it?

- Intersect (intersect)
 - Return the rows that appears in both tables
- Except (except)
 - Return the rows that appear in the first table but not the second one
 - Sometimes written as minus in some database products
- However, they are not used as much as union
 - intersect <--> inner join
 - except <--> left outer join with an "is null" condition

Subquery

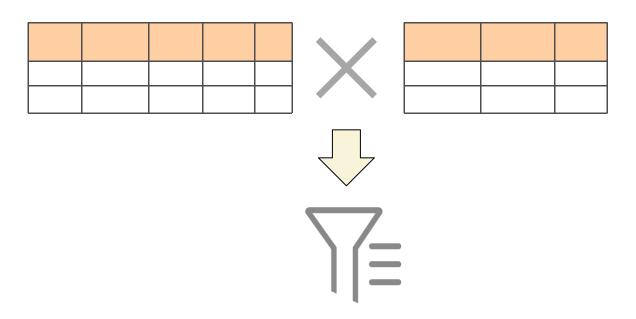

Subquery

- We have used subqueries after from before
 - ... in order to build queries upon a query result
- And, we can add subqueries after select and where as well

Subquery after Select

- Example: show titles, released years, and country names for non-US movies
 - Solution 1: Join

```
select m.title, m.year_released, c.country_name
from movies m join countries c
on m.country = c.country_code
where m.country <> 'us';
```

Subquery after Select

- Example: show titles, released years, and country names for non-US movies
 - Solution 2: Nested selection

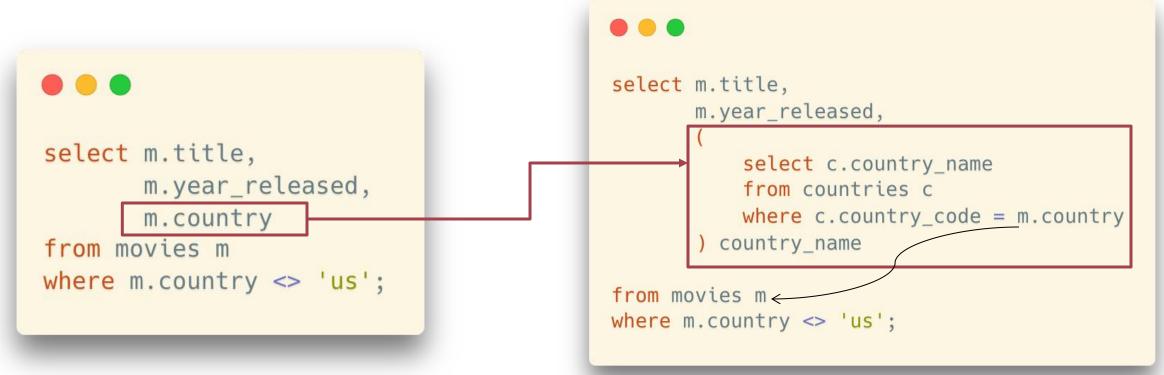

... still a country code though

 How can we replace it with the country name?

Subquery after Select

- Example: show titles, released years, and country names for non-US movies
 - Solution 2: Nested selection

A subquery after select:

 For each selected row in the outer query, find the corresponding country name in the countries table

- Recall: the in() operator
 - It can be used as the equivalent for a series of equalities with OR (it has also other interesting uses)
 - It may make a comparison clearer than a parenthesized expression

```
where (country = 'us' or country = 'gb')
and year_released between 1940 and 1949
where country in ('us', 'gb')
and year_released between 1940 and 1949
```

- ... But in() is far more powerful than this
 - What is between parentheses may be, not only an explicit list, but also an implicit list of values generated by a query

```
in (select col
    from ...
    where ...)
```

- Example: Select all European movies
 - How can we specify the filtering condition?

```
select country,
year_released,
title
from movies
where [?]
```

- Example: Select all European movies
 - A horrible solution: list all European countries with or

```
select country,
    year_released,
    title
from movies
where country = 'fr' or country = 'de' or ...
```

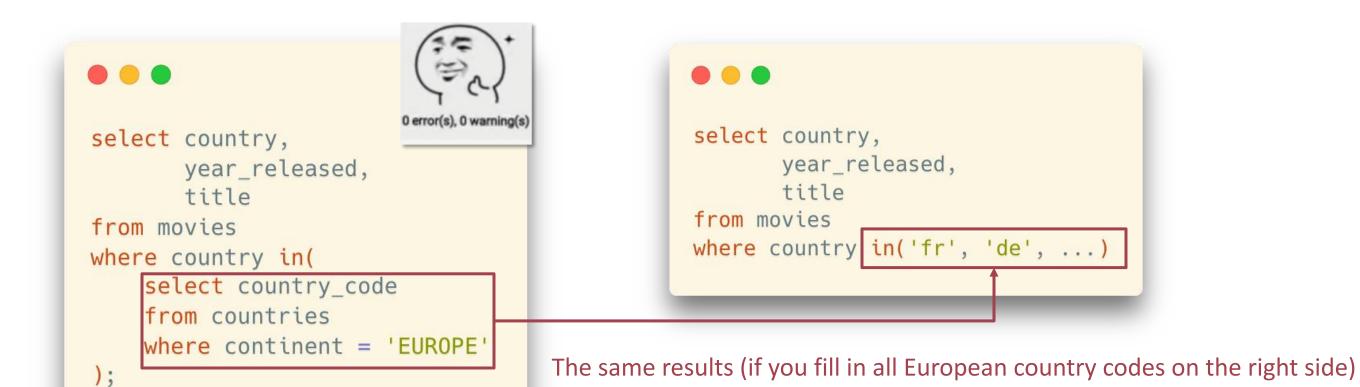

- Example: Select all European movies
 - A (slightly better) solution: list all European countries in an in operator

```
select country,
    year_released,
    title
from movies
where country in('fr', 'de', ...)
```

- Example: Select all European movies
 - A (slightly better) solution: list all European countries in an in operator

- Example: Select all European movies
 - A proper solution: (dynamically) fill in the list of country codes in an in operator

But you can automatically generate this list

Especially useful when the table in the subquery changes often

• Some products (Oracle, DB2, PostgreSQL with some twisting) even allow comparing a set of column values (the correct word is "tuple") to the result of a subquery.

```
(col1, col2) in
          (select col3, col4
          from t
          where ...)
```

- Some important points for in()
 - in() means an implicit distinct in the subquery
 - in('cn', 'us', 'cn', 'us') is equal to in('cn', 'us')

- Some important points for in()
 - in() means an implicit distinct in the subquery
 - in('cn', 'us', 'cn', 'us', 'us') is equal to in('cn', 'us')
 - null values in in()
 - Be extremely cautious if you are using **not** in(...) with a null value in it

- Some important points for in()
 - in() means an implicit distinct in the subquery
 - in('cn', 'us', 'cn', 'us', 'us') is equal to in('cn', 'us')
 - null values in in()
 - Be extremely cautious if you are using not in(...) with a null value in it

```
value not in(2, 3, null)

⇒ not (value=2 or value=3 or value=null)

⇒ value<>2 and value<>3 and value<>null

⇒ false -- always false or null, never true
```

... however, value=null and value<>null are
always FALSE:

• We should use is [not] null instead

Thus, with NULL inside, the not in() expression always returns false, and hence no row will be selected and returned.

Update and Delete

So Far...

- We have learned:
 - How to access existing data in tables (select)
 - How to create new rows (insert)
- CRUD/CURD
 - create, read, update, delete
 - In SQL: insert, select, update, delete
 - In RESTful API: Post, Get, Put, Delete
 - Necessary operations for persistent storage

- Make changes to the existing rows in a table
- update is the command that changes column values in specific ROWs (NOT columns themselves)
 - You can even set a non-mandatory column to NULL
 - The change is applied to all rows selected by the where

```
update table_name
set column_name = new_value,
    other_col = other_new_val,
    ...
where ...
```

- Remember
 - When you are doing any experiments with writing operations (update, delete), <u>backup</u>
 the data first
 - E.g., copy the tables

- Example: A nobiliary particle is used in a surname or family name in many Western cultures to signal the nobility of a family.
 - We may want to modify some names in such a way as they sort as they should.

K	< 23 rows ~ > >	S = + - 5 @ f	Tx: Auto v DDL ,	*

14	16452	Gustav	von Seyffertit	z	1862	1943	М
15	16453	Josef	von Sternberg		1894	1969	М

John von Neumann

- Example: A nobiliary particle is used in a surname or family name in many Western cultures to signal the nobility of a family.
 - We may want to modify some names in such a way as they sort as they should.
- First, how can we find these names?

- Example: A nobiliary particle (贵族姓氏) is used in a surname or family name in many Western cultures to signal the nobility of a family.
 - We may want to modify some names in such a way as they sort as they should.
- First, how can we find these names?
 - Wildcards (通配符)

```
select * from people_1 where surname like 'von %';
```

- Example: A nobiliary particle (贵族姓氏) is used in a surname or family name in many Western cultures to signal the nobility of a family.
 - We may want to modify some names in such a way as they sort as they should.
- Then, how should we update the names?

Try the transformation with select:

```
select replace('von Neumann', 'von ', '') || ' (von)';
1 Neumann (von)
```

REPLACE(string, search_string, replacement_string)

- Example: A nobiliary particle (贵族姓氏) is used in a surname or family name in many Western cultures to signal the nobility of a family.
 - We may want to modify some names in such a way as they sort as they should.
- Finally, the update statement:

This could be used to postfix all surnames starting by 'von' with '(von)' and turn for instance 'von Stroheim' into 'Stroheim (von)'

```
-- Specify the table update people

-- Set the update rule set surname = replace(surname, 'von ', '') || ' (von)'

-- Find the rows that need to be updated where surname like 'von %';
```

- The where clause specifies the affected rows
 - However, you can use update without where, where the updates will be applied to all
 rows in the table
 - Use with caution!
 - Sometimes, there will be a warning in IDEs such as DataGrip

- The update operation may not be successful when constraints are violated
 - For example, update the primary key but with duplicated values

[23505] ERROR: duplicate key value violates unique constraint "people_pkey" Detail: Key (peopleid)=(1) already exists.

 This is why we need constraints when creating tables: avoid unacceptable writing operations that break the integrity of the tables

- Subqueries in update
 - Complex update operations where values are based on a query result
- Example: Add a column in people table to record the number of movies one has joined (either directed or played a role in)

- Example: Add a column in people table to record the number of movies one has joined (either directed or played a role in)
 - First, how do we count the movies for a person?
 - (Used as the subquery part in the update statement)

```
select count(*) from credits c where c.peopleid = [some peopleid];
```

- Example: Add a column in people table to record the number of movies one has joined (either directed or played a role in)
 - First, how do we count the movies for a person?
 - (Used as the subquery part in the update statement)
 - Then, let's update the data

```
update people p

set num_movies = (
    select count(*) from credits c where c.peopleid = p.peopleid
)

where peopleid < 500;
-- This where is only for testing purpose;
-- You should change it (or remove it) when in actual use.</pre>
```

Delete

• As the name shows, delete removes rows from tables

```
delete from table_name where ...
```

- If you omit the WHERE clause, then (as with UPDATE) the statement affects all rows and you end up with an empty table!
- Well,
 - many database products provide a roll-back mechanism when deleting rows
 - Transactions can also protect you (to some extent)

Delete

- One important point with constraints (foreign keys in particular) is that they guarantee that data remains consistent
 - They don't only work with insert, but with update and delete as well.
 - Example: Try to delete some rows in the country table

[23503] ERROR: update or delete on table "countries" violates foreign key constraint "movies_country_fkey" on table "movies" Detail: Key (country_code)=(us) is still referenced from table "movies".

Foreign-key constraints are especially useful in controlling delete operations

Constraints

- This is why constraints are so important:
 - They ensure that whatever happens, you'll always be able to make sense of ALL pieces of data in your database.

- How can we DELETE a row referred to as FOREING KEY anyway?
 - CASCADE Delete
 - Remove the Foreign Key Constraint
 - Manually Delete or Update the Child Table Rows
